

Autoplay on Trial: An Online Experiment on the Suspect Behind Excessive Screen Time

Reha Tuncer*

August 11, 2025

Abstract

Interface design features can ‘nudge’ consumers to take certain actions and are often accused of promoting addictive online behavior. A prevalent design feature across popular social media and streaming platforms is the autoplay default. We present an incentivized online experiment to investigate whether the autoplay feature can cause an increase in undesired video consumption, and elicit the willingness to pay for commitment against autoplay. In a two-day study, we recruited a total of 236 participants to allocate 20 minutes between two tasks: Transcribing meaningless characters and watching funny animal videos. Time allocation decisions were planned a day before and realized on the next day. We randomly assigned participants to either autoplay or click-to-play media controls while keeping the video content constant. We find that the autoplay feature,

*I am grateful to Ernesto Reuben and Kerstin Bongard-Blanchy for their guidance in the design and conception of this experiment, to Sophie Doublet for her help in interface design, and to Suvadeep Mukherjee for his guidance in building web experiments. I thank Vincent Koenig for financial support. I also thank participants at the Behavioral Economics Summer School at the University of Copenhagen, the doctoral workshop at UC Louvain, the Experimetrics Workshop Soleto at Sapienza University Rome, as well as Samuel Greiff, Manuel Munoz, Hande Erkut and numerous colleagues for helpful comments. All errors remain my own.

in isolation, does not override participants’ planned time allocation for media consumption. In addition, participants exhibit a positive willingness-to-pay for autoplay (6.72 pence/hour), perceiving it as a convenience feature rather than a self-control problem in our setting. Experimenter demand effects and lack of content appeal result in participants allocating more time to the transcription task than planned, confounding the effect of the autoplay treatment. These results suggest that design features promoting potentially addictive behavior like autoplay are better studied in field settings where content consumption occurs naturally alongside algorithmic personalization.

1 Introduction

Autoplay is a design feature that automatically provides users with new video content without any action. It has become a familiar sight in the user interfaces of major social media and streaming platforms over the last decade,¹ and has been described as a default nudge that reduces the autonomy of users (Lukoff et al., 2021; Schaffner et al., 2023). Autoplay’s widespread adoption and concerns about its restriction of users’ freedom of choice have also attracted regulatory scrutiny, with the U.S. SMART Act proposing to ban platforms from serving autoplay content “without an express, separate prompt by the user” due to its contribution to addictive online behavior.²

While autoplay is pervasive and tends to increase viewing times (Chen et al., 2025; Hiniker et al., 2018; Schaffner et al., 2025), its impact on user welfare and the mechanisms driving this effect are not well understood. Does the increase in consumption go against users’ wishes, or does it merely remove frictions to help them achieve their desired consumption levels? Can we attribute the increase in consumption to autoplay in isolation, or does it also depend on the supply of content? To isolate the causal effect of autoplay on content consumption and its welfare consequences, we designed an

¹As of 2025 these platforms include Facebook, Instagram, Netflix, YouTube, TikTok, and Twitter (currently X). Twitter [first introduced](#) autoplay in 2015, and described it as a means to reduce “extra effort” in the number of clicks/taps required to consume content.

²SMART Act of 2019, S. 2314, 116th Congress.

experiment holding constant the video content displayed to users while eliciting their preferences related to content consumption before the actual consumption occurs.

We dedicated the first block of the experiment to measure the differences between planned and realized allocations. We recruited 184 participants who allocated 1200 seconds (20 minutes) between two tasks. The tasks involved seconds of transcription of random character sequences at 0.15 pence/second, and seconds of watching funny animal videos at 0.1 pence/second. On the first day, participants got familiar with tasks and made planned allocations using the strategy method. On the following day, participants realized their time allocation decision without constraints.

To isolate the causal effect of autoplay on the realized time allocation decisions, we randomly assigned participants to either the *Autoplay* or *Control* condition. In the *Autoplay* condition watching task videos played continuously. In the *Control* condition participants explicitly clicked to play each video. We held constant the content by presenting 80 manually curated “funny animal” videos from YouTube and TikTok in identical sequence. This eliminated algorithmic content curation and personalization as potential confounds.

In a second block of the experiment, we modified the design to elicit demand for a commitment device. We recruited 52 additional participants who made binary choices over their preferred autoplay setting (on or off) for nine bonus payments ranging from 5 to 50 pence. We implemented one of these decisions at random, determining both the autoplay setting for the next day and the associated bonus payment. This allowed us to measure participants’ Willingness To Pay (WTP) for autoplay in advance, providing insight into whether participants viewed the feature as beneficial (positive WTP) or as a self-control problem requiring a commitment device (negative WTP).

We report five key findings. The first set of results focuses on our preregistered hypothesis that autoplay would cause an increase in video content consumption. We find no evidence supporting this hypothesis. Participants in the *Autoplay* condition watched statistically indistinguishable numbers of videos compared to the *Control* condition. *Autoplay* condition also had no significant effect on the proportion of time spent on

either task. These results also hold for other engagement metrics (i.e., average session length, number of sessions).

Second, participants viewed autoplay as beneficial rather than problematic. Contrary to our hypothesis that participants would demand commitment devices against autoplay, we find a positive WTP for the feature. Using data from the second block, we estimate an average WTP of 6.72 pence/hour. Autoplay is considered as a convenience feature rather than as a threat to self-control, aligning with earlier research ([Bongard-Blanchy et al., 2021](#); [Schaffner et al., 2025](#)).

Third, comparing planned time allocations to realized ones, we find that participants consumed significantly less content than their day 1 plans implied in both conditions. The decrease amounts to 35% less time spent on the watching task. This result is driven by 33% of all participants who had planned to spend up to three quarters of their time watching videos but instead decreased their content consumption on the next day. On the other end, 88% of those who had initially planned to spend less than a quarter of their time watching videos successfully followed their plans, matching their planned time allocations.

Fourth, evidence from a regression discontinuity analysis shows that participants monitored their day 1 plans despite ultimately exceeding them. When participants reached their planned transcribing duration, they immediately reduced transcribing probability by 25.5 percentage points in the next 60-second window. However, this effect dissipated quickly and became statistically insignificant within 90 seconds as participants resumed transcribing.

Finally, a mixed-methods analysis of open-ended responses reveals that participants perceived the experimental environment as a work setting rather than a choice between independent tasks. While 29% spontaneously described transcribing using negative terms, another 23% characterized video-watching as “taking breaks” from work. This suggests that experimenter demand effects may have confounded the intended effects of the autoplay treatment, with implications for both the interpretation of our null results and the broader generalizability of our study.

98 A primary internal validity concern is that experimenter demand effects favored 98
99 allocating more time to the transcribing task than planned. Such effects can emerge 99
100 through contextual cues and alter participant behavior by drawing attention to variables 100
101 of interest (Zizzo, 2010). In our experiment, these could include (i) the small earnings 101
102 difference favoring the transcribing task,³ (ii) multiple mentions of the quality criteria for 102
103 the transcribing task to receive earnings, (iii) placement of the transcribing task as the 103
104 first activity upon starting a session, and (iv) the time allocation slider framing decisions 104
105 as time spent on the transcription task. Alternative designs could have addressed these 105
106 concerns by rewarding balanced time allocations more, eliminating earning differences 106
107 altogether, or displaying both tasks right next to each other. 107

108 Another major challenge in isolating the effects of autoplay is the role of content 108
109 appeal. Higher content appeal would make the watching task more tempting, and create 109
110 a stronger tradeoff between the two tasks. To address this while keeping the content 110
111 identical across conditions, we conducted pretests from the same participant pool where 111
112 the funny animal videos came out as the most popular theme. Participants also rated 112
113 the curated videos positively (median 7/10) in a post experiment survey. Regardless, the 113
114 watching task content may not have been sufficiently appealing. Allowing participants 114
115 to select among a list of themes with manually curated videos could have addressed this 115
116 issue (Ek & Samahita, 2023). 116

117 A final concern in online experiments is ensuring genuine participation equivalent to 117
118 laboratory conditions. We implemented several measures to address this challenge. We 118
119 used JavaScript-based attention monitoring to detect each second participants navigated 119
120 away from the experimental interface following (Purohit et al., 2023). We also required 120
121 minimum internet speeds and restricted participation to desktop users with Chromium- 121
122 based browsers to standardize the user experience. Participants also answered post- 122
123 experiment survey questions about their engagement while watching videos and about 123

³This difference is 60 pence over 20 minutes, equivalent to a 1.8 pound hourly wage difference (15% above our 12 pound minimum wage baseline). We hypothesized that in the absence of an earnings difference, participants would not work on the transcription task.

connection interruptions. These controls ensured that our final dataset is composed of participants who were active, and approximate the controlled conditions of laboratory experiments (Arechar et al., 2018).

We contribute to several strands of literature. First, the literature on studying the effects of social media and streaming services on user well-being (Allcott et al., 2020, 2022; Bao, 2025; Beknazar-Yuzbashev et al., 2025; Braghieri et al., 2022; Bursztyn et al., 2023; Collis & Eggers, 2022; Groshek et al., 2018; Nyhan et al., 2023; Purohit et al., 2023; Walton-Pattison et al., 2018). We contribute to this work by shedding light on one potential driver of the harmful effects of social media and streaming services, the autoplay, in a controlled setting.

A subset of this literature focuses on the effects of specific interface design elements on user behavior, particularly related to user agency and overconsumption of content (Bongard-Blanchy et al., 2021; Chen et al., 2025; Hoong, 2021; Lukoff et al., 2021; Lupiáñez-Villanueva et al., 2022; Lyngs et al., 2019, 2020; Mathur et al., 2021; Schaffner et al., 2023, 2025; Silverman et al., 2024). To our knowledge, our paper provides the first attempt at isolating the causal effects of autoplay on content consumption.

Methodologically, this paper contributes to the literature on laboratory experiments that observe behavior in real time while participants trade cognitive effort with leisure (Bhatia et al., 2021; Bonein & Denant-Boèmont, 2015; Ek & Samahita, 2023; Houser et al., 2018; Kool & Botvinick, 2014). We also add to a burgeoning literature manipulating design elements within the user interface to reduce overconsumption of content (Hiniker et al., 2018; Lyngs et al., 2020; Purohit et al., 2023; Schaffner et al., 2025).

The remainder of this paper is organized as follows. Section 2 describes the experimental design. Section 3 details the experimental sample and procedures. Section 4 presents our results and Section 5 concludes.

2 Design

2.1 Timeline and Session Structure

We conducted a two-day online lab experiment to examine how autoplay feature affects time allocation between transcription of random characters and watching funny animal videos. The multi-day structure allowed us to measure the gap between planned and actual behavior, a key feature in research on present-focused preferences (Ericson & Laibson, 2019). Participants completed two separate data collection sessions with a cooling-off period of 24 hours between sessions.

Day 1 sessions included a practice session to familiarize participants with the experimental interface, followed by planned time allocation decisions. Day 2 featured the main session where participants made actual time allocation decisions. We conducted two waves of data collection during May 2023, as described in Table 1.

Table 1: Summary of timeline and session structure

	Practice Session	Multiple Price List	Time Choice	Main Session	Decision Horizon
Day 1 (Block 1)	✓		✓		24-hour
Day 2 (Block 1)				✓	immediate
Day 1 (Block 2)	✓	✓	✓		24-hour
Day 2 (Block 2)				✓	immediate

Note: This table shows the experimental components administered across two data collection waves, with columns ordered chronologically within each day. The first block established differences in planned and actual time allocations across conditions, while the second block incorporated the Multiple Price List to measure demand for commitment against autoplay. Decision horizon refers to the period between planned time allocation and the main session.

161 2.2 Technical Implementation and Interface Design 161

162 We designed the experimental platform to provide precise control over the testing en- 162
163 vironment. We presented both tasks within a single web page using distinct tabs, al- 163
164 lowing participants to switch between transcribing and watching videos seamlessly while 164
165 preserving progress. A progress bar and timer provided feedback for remaining time. 165
166 Sessions began with the transcription task as the default, requiring an active choice to 166
167 switch to the watching task. 167

168 The interface incorporated several key features to track behavior. We logged all crit- 168
169 ical interactions including tab switches, keystrokes during transcription, video controls, 169
170 and cursor movements outside the experimental window. This granular tracking enabled 170
171 us to construct detailed measures of attention and engagement across tasks. 171

172 2.3 Internal Validity Controls 172

173 Online experiments present unique challenges for maintaining experimental control, in- 173
174 cluding participant multitasking, technical disruptions, and environmental variation. We 174
175 implemented comprehensive measures to address these concerns and ensure data quality. 175
176 We clearly communicated these restrictions to participants at the experiment’s outset. 176

177 **Participant and Technology Screening:** We selectively admitted participants 177
178 using multiple screening criteria to ensure a stable experience. Internet speed require- 178
179 ments filtered out participants with unstable connections (minimum 30 Mbps for block 179
180 1, 40 for block 2). We restricted participation to users with Windows, Linux, or Mac 180
181 operating systems using Chromium-based browsers exclusively. We excluded Safari and 181
182 Mozilla Firefox due to restrictive autoplay configurations. Mobile devices and tablets 182
183 were prohibited to standardize the user experience. 183

184 **Platform Controls:** The experimental website enforced linear navigation, prevent- 184
185 ing participants from moving backward through the experiment. We disabled right-click 185
186 functions and keyboard shortcuts. Any attempt to navigate backward reset progress to 186
187 the landing page. 187

188 **Attention and Engagement Monitoring:** We implemented real-time tracking 188

of participant attention using a JavaScript library to detect interface visibility disruptions.⁴ This system captured actions such as minimizing the browser, switching between web pages, or launching other applications. The tracking provided second-by-second measures of participant engagement.

Post-Experiment Validation: After completing the experiment, participants reported any connectivity disruptions and confirmed their genuine engagement with the watching task. We combined these self-reports with our tracking measures to identify and filter data potentially compromised by distractions or divided attention.

2.4 Tasks

2.4.1 Transcription Task

The transcription task requires transcribing successive CAPTCHAs. CAPTCHAs are computer-generated images that contain random letters, numbers and randomly placed white spaces.⁵ Each CAPTCHA has a total length of 35 characters, including the white spaces. Participants spent on average 41 seconds per CAPTCHA.

We designed the images to be blurred and distorted by lines and dots added on top to increase comprehension difficulty.⁶ The interface always presents these CAPTCHA images with a text box and a submit button. When the submit button is clicked, the next CAPTCHA image appears and the text input for the previous one is stored. The task is identical across conditions, as illustrated in Figure 1.

We established easy-to-meet quality requirements to ensure participants remained active. These requirements include an overall transcription accuracy of at least 70 percent in submitted CAPTCHAs⁷ and a minimum of one CAPTCHA submission per minute

⁴See more information about the [Intersection Observer API](#).

⁵We added white spaces to improve readability after pretests. The number of white spaces was limited to a maximum of 5 instances per CAPTCHA to control the transcribing time per image.

⁶The [randomization procedure](#) to generate CAPTCHAs.

⁷We use Python’s [difflib](#) string-matching algorithm to measure accuracy. It consists of finding the longest common substring and then finding recursively the number of matching characters in the non-matching regions on both sides of the longest common substring. Overall accuracy of 70 percent

211 spent on the task. Participants had to meet these quality requirements to receive com- 211
 212 pensation for the transcription task. 212

Figure 1: Transcription task tab

Note: This figure describes the transcription interface tab. As participants always begin in the transcription tab by default, there is a banner that reminds participants to click the tab buttons to switch tasks. This banner disappeared as soon as participants switched tasks once.

213 2.4.2 Watching Task 213

214 In this task, participants watch successive short videos in a customized media player. The 214
 215 video content and the order in which videos appear to participants are identical across 215
 216 conditions. We completely disabled the media player controls: participants cannot skip 216
 217 videos (user scrolling is disabled) or use the media player’s slider to advance or go back 217
 218 in a particular video. 218

219 The conditions differ in their autoplay functionality. In the *Autoplay* condition, 219
 implies an average of 10.5 ($0.3 * 35$) mistakes across all submitted CAPTCHAs.

220 videos play automatically when the watching tab is visible and pause with a click any- 220
 221 where on the video. The media player keeps scrolling to the next videos and continues 221
 222 playing them unless interrupted. In the *Control* condition, participants need to have the 222
 223 watching tab visible and click on each consecutive video to play them. At the end of 223
 224 each video, the scrolling animation brings the next video that only starts playing when 224
 225 the participant clicks on it. Figure 2 illustrates the video tab in the *Control* condition. 225
 226 We manually selected 80 videos to avoid algorithmic biases resulting from the rec- 226
 227 ommender system’s personalized suggestions. We curated videos from YouTube and 227
 228 TikTok, using the tags “funny animal” and “cute animal”. We chose animal videos 228
 229 because of their popularity during pretests.⁸ We reviewed the selected videos to ensure 229
 230 that they did not contain any harmful or violent actions toward the animals involved. 230
 231 To maximize the frequency of experiencing the autoplay feature during the watching 231
 232 task, we kept the first 60 videos shorter (mean 12.25 seconds, SD 7.04 seconds), with 232
 233 the last 20 videos longer than the rest (mean 25.50 seconds, SD 14.04 seconds). 233

⁸During the pretests, the experiment was followed by a separate questionnaire asking participants to
 rate the videos they had seen and suggest what types of videos they would have liked to see more of,
 with options including sports, news, or trending content.

Figure 2: Watching Task tab

Note: This figure describes the “Watch” tab in the *Control* condition. Before the first video is clicked upon to be played, there is a banner that reminds participants that the video won’t play without clicking. This banner was not present in the *Autoplay* condition and videos started playing as soon as participants clicked on the “Watch” tab seen on the top right side. Notice that the top part of the following video is already visible in the bottom part of the screen.

2.5 Practice Session

The experiment consists of two sessions during which participants interact with the tasks described above. The first session is the practice session on day one. It comes right after the written descriptions of each task and serves to familiarize participants with the tasks and the interface. Participants are assigned to either *Autoplay* or *Control* condition before the practice session, so that they experience the same video interface

on both the practice and main sessions.

Practice session was 2 minutes long. Each task was available for only 60 seconds and participants were not allowed to switch between tasks. On the first tab, participants were required to retype CAPTCHAs. The 60-second period was enough to submit one CAPTCHA and see the second CAPTCHA image. After 60 seconds, a pop-up appeared on the screen blocking any other interaction and taking participants to the second page.

Participants were required to close this pop-up to advance to the second task. The rationale behind the pop-up was to ensure participants spent equal time on both tasks. Whether or not this pop-up was closed was verified and served as an additional attention check.⁹ Once closed, the watching task began for 60 seconds, enabling participants to watch 4 to 5 short videos depending on whether they were assigned to the *Autoplay* or the *Control* condition.

2.6 Multiple Price List

In the second block of the experiment, we used a Multiple Price List to elicit the Willingness to Pay for commitment against autoplay, commonplace method in the literature (Andersen et al., 2006; Jack et al., 2022). After the practice session on day one, participants made 9 binary decisions, choosing between their preferred media player setting (autoplay off or on) and a bonus payment (see Figure 3). We determined bonuses by the per-second earning differences across tasks, multiplied by the expected differences in time spent between the conditions in the first block of the experiment.

Specifically, we expected the average difference between the *Autoplay* and *Control* conditions, in terms of time spent across tasks, to be in the magnitude of 60 seconds (it was 79.5 seconds, from Table 3). This resulted in an average earning difference of $60 * (0.15 - 0.1) = 3$ pence. To capture this in the MPL choices offered, we set the symmetric bonuses accordingly: £[0.05, 0.1, 0.25, 0.5].

We used the Becker-deGroot-Marschak (Becker et al., 1964) random price mechanism for incentivization. Once the binary decisions were completed, we randomly implemented

⁹All participants closed this pop-up and switched to the watching task.

one of their 9 choices and informed participants whether autoplay would be on or off,
and of their associated bonus earnings. With this knowledge, participants then made
their planned time allocation for day 2.

Figure 3: Multiple Price List page

Autoplay on or off?

In the practice session videos played automatically with **Autoplay**. There is another version **where you need to click on videos to play them**.

You need to make 9 decisions about Autoplay. One of your decisions will be randomly chosen and implemented. **You will receive a bonus payment and watch videos with the chosen Autoplay setting.**

For example, if you choose Autoplay for the first decision and it is implemented, you will have Autoplay and receive an additional £0.5 bonus payment.

▶ AUTOPLAY +£0.5	⏸ NO AUTOPLAY +£0
▶ AUTOPLAY +£0.25	⏸ NO AUTOPLAY +£0
▶ AUTOPLAY +£0.1	⏸ NO AUTOPLAY +£0
▶ AUTOPLAY +£0.05	⏸ NO AUTOPLAY +£0
▶ AUTOPLAY +£0	⏸ NO AUTOPLAY +£0
▶ AUTOPLAY +£0	⏸ NO AUTOPLAY +£0.05
▶ AUTOPLAY +£0	⏸ NO AUTOPLAY +£0.1
▶ AUTOPLAY +£0	⏸ NO AUTOPLAY +£0.25
▶ AUTOPLAY +£0	⏸ NO AUTOPLAY +£0.5

Please pick your favorite option for each row.

CONTINUE

Note: This figure describes the MPL page where participants made 9 binary choices between their preferred autoplay setting and bonus payments. Each row presents a choice between “Autoplay” (left) and “No Autoplay” (right) with associated bonus amounts ranging from £0.05 to £0.5. Note that participants in this block only saw autoplay videos in the practice session, and stated their preferences accordingly. The interface required participants to select one option in each row before proceeding. One of these 9 decisions was randomly selected for implementation in the main session, determining both the autoplay setting and any bonus payment for day two.

2.7 Time Choice

Following the practice session, participants proceeded with the time choice section. This section required them to specify their preferred time allocation between the two tasks for the day 2. Participants were informed the main session would be 20 minutes long and they were free to choose corner solutions, even if that meant focusing solely on one task.

We designed a slider tool with 20-second steps for participants to indicate their time allocation preferences. Initially, the slider appeared grayed out and required a click to activate. This design aimed to ensure participants considered their choices in an active manner. The click-to-activate design had two benefits: It guaranteed participants interacted with the slider and helped participants understand the task-related payoff structure.

To incentivize this decision, we randomly made 5% of the day 1 choices binding in the main session. Binding choices led to payments based on the initial time choice, but only if participants met the quality standards described under Section 2.4.1 during day 2. We excluded data from these participants from the final dataset accordingly.

The time choice served as a benchmark for participants, and participants accordingly received a reminder of it on day two. The time choice section offers insights into participants' informed time preferences and allows verifying their commitment to these choices after a 24-hour period.

Figure 4: Time Choice page

Time Choice

Now decide how long you would like to spend **tomorrow** on **Typing** and on **Watching Videos**.

Tomorrow you will have **20 minutes** for both tasks.

1 out of every 20 participant will be **bound** by the choice they made today.

Please **click on the slider** and indicate your **Time Choice**:

i You choose to spend **10 minutes 0 seconds** to **Type**.
 You choose to spend **10 minutes 0 seconds** to **Watch Videos**.
 You would earn **£4.25**.

Tomorrow you will learn whether your **Time Choice** is binding.

CONTINUE

Note: This figure shows the time choice interface with a slider tool with 20-second steps allowing participants to allocate time between the two experimental tasks for the following day’s main session. The slider initially appears grayed out and requires a click to activate. Real-time feedback shows the selected allocation (here, 10 minutes each) and expected earnings (£4.25). The interface informs participants that 1 out of 20 (5 percent) will be bound by their choice and that they will learn whether their choice is binding on day two.

2.8 Main Session

The main session took place on day two, approximately 24 hours after the time choice. We began by reminding participants of their previous day’s time allocation and informing them whether their time choice was binding. 95% of participants were free to allocate their time on day 2 as they preferred.

The main session lasted 20 minutes. Participants could switch between the transcription and watching tasks at any time using the tab interface. Unlike the practice session, there were no time restrictions on individual tasks. Participants had complete autonomy over their time allocation decisions, and could monitor remaining time through the progress bar and the timer. Throughout the main session, we monitored writing and

transcribing actions in real-time.

The treatment was implemented through the media player’s autoplay functionality as previously described in Section 2.4.2.

2.9 Hypotheses

User interface design choices are “not separable from other content choices, since their effect depends on where the platform has positioned its content on the underlying content manifold.” (Kleinberg et al., 2022). If content has very low inherent appeal and stickiness, autoplay may have minimal effect on video consumption. An analogy is how introducing breaks would have little impact on engagement for low-stickiness content like documentaries, but dramatically reduce engagement for high-stickiness content like celebrity gossip.¹⁰ Assuming that our selection of videos have sufficient appeal and stickiness, *Autoplay* condition leads to consumption beyond users’ stated preferences, creating a measurable gap between planned the time allocation and actual behavior.

Hypothesis 1: *Autoplay* condition decreases the realized time allocated to the transcription task while increasing video consumption. We test this using a linear regression:

$$Y_i = \alpha + \gamma \text{Autoplay}_i + \beta \text{TimeChoice}_i + \delta(\text{Autoplay}_i \times \text{TimeChoice}_i) + \epsilon_i \quad (1)$$

where Y_i represents our outcome variables of interest (proportion of time spent on transcription or number of videos watched), Autoplay_i is a binary indicator for the condition, and TimeChoice_i is the standardized proportion of time participants planned to spend on transcription on day 1. We estimate this model with and without the interaction term to examine whether the effect of autoplay varies based on initial time allocation plans. We expect $\gamma < 0$ for transcription and $\gamma > 0$ for videos watched.

Hypothesis 2: *Autoplay* condition has an effect on deviations from stated time allocation preferences (actual minus planned time spent on transcription). We test this using a two-sample t -test comparing the means between the two conditions.

¹⁰See Bao (2025) for recent work on addictive short drama series.

We expect the effect of autoplay on content consumption is known by participants, although they will underestimate how much they would be affected on average (Bongard-Blanchy et al., 2021). We will estimate a demand for a commitment device driven by “sophisticated” participants, i.e., a subset of participants who are aware of the effect of autoplay, in line with the literature (Ericson & Laibson, 2019).

Hypothesis 3: If participants are aware of their self-control issues, they should exhibit negative Willingness To Pay (WTP) for autoplay, preferring the commitment devices that restrict automatic video transitions. We test this using a logistic regression:

$$Y_{ij} = \beta_0 + \beta_1 \text{Bonus}_{ij} + \epsilon_{ij} \quad (2)$$

where Y_{ij} is the binary choice of taking autoplay given the bonus j from the MPL for individual i . We calculate the WTP for autoplay as the sample-averaged effect of bonus $-\beta_0/\beta_1$, and expect a negative sign indicating preference for commitment against autoplay.

In sum, these hypotheses test whether interface design features can systematically distort optimal time allocation decisions in a setting where participants face monetary incentives favoring the transcription task.¹¹

3 Sample and Procedures

The experiment was run entirely online, using widely available open-source tools.¹² We sampled from the Prolific participant pool, an online recruitment platform commonly used for academic research, and targeted adult British residents. We further imposed the following criteria: Fluency in English, balanced gender representation, and having a stable internet connection. We did not allow mobile devices and restricted access to the experiment to Chromium-based browsers to enhance the internal validity as previously discussed in Section 2.3. Only participants who succeeded on both attention checks,

¹¹Access the preregistered hypotheses. Our preregistration included hypotheses 1 and 3. We have added supporting hypothesis 2 regarding our expectations about the time choice section later.

¹²We used the MERN stack to develop and host the website in an entirely free way.

347 reported not having engaged in other activities, and did not have connection issues 347
348 during the experiment were included in the final dataset. 348

349 Payment was calculated based on actual time spent on each task during the main 349
350 session on day 2, with compensation rates of 0.15 pence per second for transcription and 350
351 0.1 pence per second for watching. Participants needed to meet the established quality 351
352 requirements for the transcription task to receive compensation for time spent on that 352
353 activity. The session concluded automatically after 20 minutes, and participants received 353
354 their final payment calculation before completing the experiment. Participants received 354
355 a fixed participation fee of £2.75. The study took less than 30 minutes in total across 355
356 2 days, with average earning per participant at £4.08. This amounted to an average 356
357 payment of £1.33 (median £1.49) for the main session. Participants who completed all 357
358 required elements received payment within seven days after the second session.¹³ 358

359 For the first block of the experiment, we preregistered a two-sample parallel design 359
360 using our prototype data and tested for equality of means across conditions. We found 360
361 that the required sample size to test [Hypothesis 1](#) with the usual parameter values 361
362 ($\alpha = .05$, $\beta = .2$) would be 114 per condition, with an effect size of 65 seconds calculated 362
363 by the difference in the average time spent between conditions ($\mu_{Autoplay} - \mu_{Control}$) and 363
364 population standard deviation of 165 seconds. Since attrition in longitudinal experiments 364
365 is commonplace, we invited 301 participants on the first day. On day two, we invited 365
366 the same 301 participants and received 276 complete responses (91% response rate). No 366
367 participants failed the attention checks more than twice.¹⁴ We dropped 17 participants 367
368 who self-reported having connection issues and 24 additional participants who stated 368
369 having engaged in other activities. We also removed 11 participants who had their 369
370 time choice enforced randomly. Finally, we removed 40 participants that were detected 370
371 to spend more than 20 consecutive seconds away from our experimental platform who 371
372 disproportionately come from the *Autoplay* condition. These 40 participants all reported 372
373 engaging with videos but had their mouse detected outside the experiment window, 373

¹³[Prolific payment policy](#) gives researchers 21 days to transfer funds to participants. The typical delay between study completion and payment is however only 3 to 4 days on average.

¹⁴Minimum requirement by [Prolific attention check policy](#).

374 making it impossible to distinguish whether they genuinely watched videos or browsed 374
375 other tabs/windows during the study (see Appendix Table [A.1](#)). The final dataset on 375
376 which we base the analysis consisted of 184 individuals. Table [2](#) shows the demographic 376
377 characteristics of the observed individuals. 377

Table 2: Balance table for the sample

	Autoplay N = 79	Control N = 105	<i>p</i> [A = C]
<i>Gender</i>			
Female	36 (45.57%)	53 (50.48%)	0.510
<i>Age</i>			
Mean (SD)	42.63 (11.70)	42.03 (11.24)	0.725
<i>Employment</i>			
Employed (full time)	45 (56.96%)	57 (54.29%)	0.718
Employed (part time/self)	23 (29.11%)	25 (23.81%)	0.417
Not employed	11 (13.92%)	23 (21.90%)	0.167
<i>Income</i>			
Low (0-15)	24 (30.38%)	32 (30.48%)	0.989
Middle (15-50)	42 (53.16%)	61 (58.10%)	0.505
High (50+)	13 (16.46%)	12 (11.43%)	0.325
<i>Marital Status</i>			
Married/Partnership	43 (54.43%)	52 (49.52%)	0.510
Single	31 (39.24%)	46 (43.81%)	0.534
Previously married	5 (6.33%)	7 (6.67%)	0.927

Note: This table presents demographic characteristics for the sample of 184 participants across conditions. Income categories are presented in thousands of British pounds. Employment categories: “Not employed” includes unemployed (looking and not looking) and homemaker. “Previously married” includes divorced, widowed, and separated. *p*-values for binary outcomes are from two-sample tests of proportions; for continuous variables, from two-sample *t*-tests. For employment, part-time and self-employed are together as one category. The sample demonstrates successful randomization with balanced participant characteristics across the conditions.

379 before and invited 60 participants on day one. On day two, we received 57 complete 379
380 answers (95% response rate). Once again, no participant failed the attention checks. No 380
381 participant reported having connection issues. We dropped 5 participants who reported 381
382 having engaged in other activities. As we were interested in the demand for a commit- 382
383 ment device, participants did not have their Time Choice enforced in this treatment. We 383
384 therefore ended up with 52 individuals in the final MPL dataset (see Appendix Table 384
385 [A.2](#) for a comparison with the main sample). 385

386 4 Results 386

387 4.1 Does Autoplay increase video consumption? 387

388 We test our primary hypothesis that autoplay increases video consumption by compar- 388
389 ing behavior across conditions. Table 3 presents summary statistics for key outcome 389
390 variables from the 20-minute main session. Two-sample t -tests reveal no significant 390
391 differences between the *Autoplay* and *Control* conditions. 391

Table 3: Sample statistics for variables of interest

	Autoplay N = 79	Control N = 105	<i>p</i> [A = C]
<i>Time Choice</i>			
Mean (SD)	0.48 (0.31)	0.44 (0.33)	0.410
Median [Min, Max]	0.50 [0.00, 1.00]	0.50 [0.00, 1.00]	
<i>Transcription Proportion</i>			
Mean (SD)	0.65 (0.31)	0.58 (0.33)	0.173

<i>Content rating</i>			
Mean (SD)	6.96 (2.18)	6.62 (2.45)	0.327
Median [Min, Max]	7.00 [2.00, 10.00]	7.00 [0.00, 10.00]	

Note: This table presents key outcome variables from the Main Session. “Time Choice” refers to participants’ stated preferences for transcribing on day 1 (proportion), while “Transcription Proportion” represents the actual proportion of time spent on transcription task during the 20-minute Main Session on day 2. Nb. of sessions is the number of transcription or watching sessions participants completed and Session length represents the mean duration of individual sessions in seconds. Content rating reflects participants’ appreciation of video content on a 0-10 scale. *p*-values are from two-sample *t*-tests comparing experimental conditions.

To formally test [Hypothesis 1](#), the effects of the *Autoplay* condition on time spent on transcription, we run the regression specified in Equation 1. Our analysis reveals that the autoplay manipulation had no statistically significant effect on actual transcription behavior. Table 4 presents results for transcription proportion as the dependent variable. The coefficient on the autoplay ranges from 0.12 to 0.20 across specifications but remains statistically insignificant in all models (p -values > 0.16). Participants' day 1 time allocations emerge as a powerful predictor of day 2 behavior: a one standard deviation increase in planned transcription time is associated with a 0.67 standard deviation increase in actual transcription time ($p < 0.001$). Including day 1 time allocations increases the variance explained by the model, rising from 1% to 46%.

Table 4: *Autoplay* condition and time spent transcribing

	Transcription proportion (z-score)		
	(1)	(2)	(3)
Autoplay	0.203 (0.147)	0.121 (0.109)	0.119 (0.110)
Time Choice (z-score)		0.673*** (0.057)	0.651*** (0.081)
Autoplay $\times$ Time Choice			0.057 (0.110)
Constant	-0.087 (0.100)	-0.052 (0.076)	-0.053 (0.076)
Obs.	184	184	184
R^2	0.010	0.462	0.463
F -statistic	1.91	77.42	61.52

Note: Robust standard errors in parentheses. All variables are standardized. Time choice represents participants' planned transcription proportion from day 1. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

Similarly, Table 5 examines the effect on video consumption, a direct test of our primary hypothesis that autoplay would increase video consumption. Across all specifications, the autoplay coefficient is statistically insignificant. This suggests that the autoplay feature did not meaningfully alter participants' video consumption behavior. Again, day 1 plans prove to be the dominant predictor: participants who planned more transcribing watched -0.66 standard deviation fewer videos ($p < 0.001$).

Table 5: *Autoplay* condition and the number of videos watched

	Nb. of Videos Watched (z-score)		
	(1)	(2)	(3)
Autoplay	-0.053 (0.149)	0.029 (0.112)	0.031 (0.112)
Time Choice (z-score)		-0.664^{***} (0.056)	-0.619^{***} (0.079)
Autoplay $\times$ Time Choice			-0.114 (0.105)
Constant	0.023 (0.098)	-0.012 (0.076)	-0.010 (0.076)
Obs.	184	184	184
R^2	0.001	0.440	0.443
F -statistic	0.13	73.06	61.53

Note: Robust standard errors in parentheses. All variables are standardized. Time choice represents participants' planned transcription proportion from day 1. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

For completeness, we provide the regression outputs from the unrestricted dataset in Appendix Table A.3 and A.4. These include 40 participants who spent at least 20 consecutive seconds outside either task. Comparing the interaction models (column 3), we observe that the effect of the *Autoplay* condition on transcribing behavior decreases

412 from 0.119 in the restricted sample to 0.055 in the unrestricted sample. The effect of 412
413 the *Autoplay* condition on the number of videos watched increases from 0.031 in the 413
414 restricted sample to 0.132 in the unrestricted sample. However, the null results remain 414
415 unchanged across both specifications. Because we cannot ascertain the data quality for 415
416 the unrestricted sample, we base our conclusions on the restricted sample of 184. 416

417 We observe two key patterns in the data that help explain the null findings. First, 417
418 we observe contradicting results: the *Autoplay* condition increases time spent transcrib- 418
419 ing by 0.12 standard deviations (though statistically insignificant) while simultaneously 419
420 increasing the number of videos watched by 0.03 standard deviations (also insignificant). 420
421 If people type more, shouldn't they watch fewer videos? We identified a mechanical con- 421
422 found in our experimental design: the time lost during video transitions. Participants in 422
423 the *Control* condition, who had to manually click to start each new video, lost an average 423
424 of 46.52 seconds due to these transition delays whereas those in the *Autoplay* condition 424
425 lost only 1.08 seconds. This large difference of 45.45 seconds per session is statistically 425
426 significant ($t(105) = 4.89, p < 0.001$). This difference in time lost not watching videos 426
427 explains the contradicting results and underscores the importance of looking at the un- 427
428 biased outcome variable (i.e., number of videos watched) when evaluating the effects of 428
429 the autoplay feature. 429

430 Second, assuming the actual effect size for the number of videos watched lies some- 430
431 where between the restricted and unrestricted samples, our power calculations based 431
432 on pretests were insufficient: The required sample size to provide a two-sided test for 432
433 [Hypothesis 1b](#) with the usual parameter values ($\alpha = .05, \beta = .2$) would be between 300 433
434 to 5000 per treatment, with common standard deviation as the root MSE from the stan- 434
435 dardized number of videos watched variable in the third regression. Other solutions to 435
436 this power problem are design-related and involve extending the main-session duration 436
437 to above 20 minutes, or nudging participants to mix more between tasks to avoid corner 437
438 solutions (e.g., higher earnings for time allocations between .25 and .75 of either task). 438

Table 6: Seconds lost by condition

	Control	Autoplay	Difference
Total seconds lost	46.52 (9.27)	1.08 (0.65)	45.45*** (9.29)
Observations	105	79	184
<i>t</i> -statistic			4.89

Note: Standard errors are in parentheses. Time is measured as the average of seconds lost to video transitions per session. The difference was tested using a two-sample *t*-test with unequal variances. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

4.2 Autoplay and deviations from day 1 time allocation

Does the *Autoplay* condition have an effect on deviations from day 1 time choice? To assess [Hypothesis 2](#), we calculated the deviation by subtracting participants' planned transcribing proportion from their actual transcribing proportion (actual minus planned). Figure 5 shows the distribution of deviations from time choice across conditions, which appears right-skewed with positive values indicating that participants transcribed more than their day 1 allocation. Participants in the *Control* condition deviated by an average of 14.6 percentage points, while those in the *Autoplay* condition deviated by 17.3 percentage points. A two-sample *t*-test reveals no statistically significant difference between means ($t = -0.694$, $p = 0.488$). The Kolmogorov-Smirnov test similarly finds no significant difference in distributions across conditions ($D = 0.085$, $p = 0.903$). These results indicate that participants in both conditions spent more time on the transcription task than they initially planned. However, the *Autoplay* condition did not significantly alter the magnitude or pattern of these deviations. Contrary to our hypothesis, we find no evidence that *Autoplay* condition led participants to deviate toward consuming more videos.

Figure 5: Distribution of deviations from day 1 time allocation by condition

Note: This figure shows the distribution of deviations from day 1 time allocation plans, calculated as actual transcribing proportion minus planned transcribing proportion. Positive values indicate participants transcribed more than they planned. The distributions are similar across conditions, and show over-transcribing relative to initial plans.

4.3 Willingness To Pay for autoplay

Contrary to Hypothesis 3, participants exhibited positive WTP for autoplay rather than demand for commitment devices against it. We assessed the demand for commitment by comparing the share of participants choosing to turn autoplay on or off along with the associated bonus payments for each of the nine decisions in the price list. To quantify participants' WTP for autoplay, we estimate the regression specification in Equation 2, where the dependent variable is the binary choice of selecting autoplay (1) or turning it off (0), and the independent variable is the bonus amount in pounds from the MPL.

Results are presented in Table 7. The coefficient on the bonus amount is 27.97 ($p < 0.001$), indicating that participants are sensitive to the financial cost of keeping autoplay on. The WTP for autoplay is the negative ratio of the constant to the bonus coefficient: $-0.6263/27.9729 = -0.0224$ pounds, or 2.24 pence for the 20-minute session. On average, participants value autoplay at 6.72 pence/hour and would be willing to forgo

468 this amount to maintain access to the feature rather than have it turned off. Participants 468
469 in our setting did not appear to perceive a tradeoff from autoplay in increasing video 469
470 consumption. 470

Table 7: Willingness to Pay for autoplay

	(1)
Bonus (£)	27.973*** (6.277)
Constant	0.626** (0.199)
Obs.	468
Clusters	52
Pseudo R^2	0.658
Wald $\chi^2(1)$	19.86

Note: Logistic regression with standard errors clustered at the participant level in parentheses. Dependent variable is binary choice of selecting autoplay (1) or turning it off (0). Bonus amounts range from £−0.5 to £0.5. The pseudo R^2 indicates good fit. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

471 4.4 Understanding the Null Results 471

472 4.4.1 Planned versus Actual Time Allocation 472

473 Participants allocated more time to transcription than initially planned. On average, 473
474 participants planned to spend 45.5% of their time transcribing but actually spent 61.2%, 474
475 representing an increase of 15.7 percentage points ($t = 8.24$, $p < 0.001$). The entire 475
476 distribution shifted rightward (see Figure 6), with median actual transcription time 476
477 (64.3%) substantially exceeding median planned time (50.0%). 477

Figure 6: Distribution of planned vs actual time allocation

Note: This figure compares the distribution of participants' planned time allocation (Day 1) with their actual time spent transcribing (Day 2). The rightward shift demonstrates participants' systematic tendency to transcribe more than originally planned.

The pattern is more pronounced when examining individual transitions. Among 151 participants who planned to spend less than three-quarters of their time transcribing, 106 (70%) actually transcribed for three-quarters or more of the session. In contrast, among 33 participants who planned to spend three-quarters or more of their time transcribing, only 4 (12%) reduced below 75%. This asymmetric upward shift contradicts traditional models of time inconsistency, which predict succumbing to immediate temptation rather than increasing effortful work.

Table 8: Transition matrix: Planned vs actual time allocation

Actual (Day 2)	Planned (Day 1)	
	<75% transcription	≥75% transcription
<75% transcription	45 (30%)	29 (88%)
≥75% transcription	106 (70%)	4 (12%)
Total	151	33

Note: This table shows transitions between planned and actual time allocation patterns. The asymmetric pattern demonstrates systematic shift toward transcription, with 106 participants increasing transcription time versus only 4 decreasing it.

The deviation toward the more effortful transcription task is rather unexpected, and participant perceptions of the decision-making environment may have influenced their behavior. This result goes against our hypothesis that participants would deviate toward the tempting video content, and points to the need to examine it more closely.

4.4.2 Experimenter demand effects

Why did participants end up transcribing more than their day 1 plans? To understand how participants perceived the decision-making environment, we asked how they decided to allocate their time during the main session. We analyzed participants’ qualitative responses to this open-ended question using dictionary-based concept detection methods (Ash & Hansen, 2023).

We identified words related to negative perceptions of the transcription task (e.g., “tiresome”, “frustrating”, “difficult”) and break-taking behavior when switching to watching (e.g., “break”, “rest”, “relax”). Figures 7a and 7b show the frequency of these concepts in participants’ responses.

session. Figure 8a shows substantial heterogeneity in individual transcribing patterns, with transcribing periods interrupted by watching periods for participants who alternate between tasks. Dividing the session into 5-minute quarters reveals that transcribing periods become progressively shorter over time (Figure 8b), suggesting that task switching may be strategic as participants either achieve their day 1 goals or experience fatigue.

Figure 8: Time spent transcribing

Note: Panel (a) shows transcribing time for 30 random participants across the 20-minute session. Panel (b) shows average transcribing time by 5-minute periods, revealing declining transcribing duration over time.

To test whether participants use their day 1 plans as behavioral reference points, we implement a sharp regression discontinuity design using the moment participants reach their planned transcribing duration as the cutoff. We estimate the discontinuous change in the probability of choosing the transcribing task at this threshold.

Results in Table 9 show a significant immediate effect: participants are 27.4 percentage points less likely to continue transcribing in the 30-second window after achieving their plan ($p = 0.007$) and 25.5 percentage points less likely in the 60-second window

($p = 0.003$). This effect dissipates by the 90-second window, becoming statistically insignificant. These findings indicate that participants do treat plan completion as a behavioral milestone, suggesting that experimenter demand effects were not so strong as to completely override their day 1 preferences.

Table 9: Regression Discontinuity estimates on transcribing after achieving day 1 plans

	Time Window		
	30-seconds	60-seconds	90-seconds
Proportion transcribing	-0.274*** (0.101)	-0.255*** (0.087)	-0.075 (0.108)
Obs. (left)	66,786	67,985	67,119
Obs. (right)	80,270	89,006	92,999
Clusters (left)	157	154	155
Clusters (right)	154	157	161
Bandwidth	339.9	368.3	422.3

Note: This table presents robust regression discontinuity estimates of the treatment effect on task choice at the moment participants achieve their day 1 planned transcribing duration. Standard errors clustered by participant in parentheses. The outcome variable is a binary indicator for choosing the transcribing task. Running variables are binned at 30-, 60-, and 90-second intervals around the achievement threshold. All estimates use triangular kernel with MSE-optimal bandwidth selection. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

However, the discontinuity analysis reveals additional complexity. Figure 9 shows that while participants initially reduce transcribing after achieving their day 1 plans, they subsequently increase transcribing effort again. This pattern suggests that participants have indeed found the watching task less engaging than anticipated, leading them to return to transcribing despite having already met their stated preferences.

Figure 9: Linear fit for transcribing rate before and after achieving day 1 plan

Note: This figure plots the average transcribing rate across 30-second bins for participants as they approach their day 1 goal. The negative slope on the left hand side indicates participants working less and less as they approach the cutoff. The drop showcases the discontinuity where achieving the day 1 goal causes in transcribing behavior. The positive slope on the right hand side reveals another trend: As time goes on, participants tend to go back to the transcribing task and decrease their video consumption. This demonstrates participants' tendency to spend more time on the effortful transcribing task than originally planned.

5 Conclusion

This study examined whether autoplay features in isolation can override users' stated preferences for media consumption. In a two-day online experiment with 236 participants, we find no evidence that autoplay increases video consumption when content is held constant. Participants viewed autoplay favorably, exhibiting positive willingness-to-pay for the convenience it provides rather than perceiving it as a self-control problem. However, experimenter demand effects resulted in participants allocating more time to transcription than planned, confounding the intended autoplay treatment.

Our findings highlight a fundamental challenge of studying potentially addictive design features in controlled laboratory settings. Design features like autoplay appear to

derive their persuasive power from personalized content streams and algorithmic curation. In our controlled setting with identical, manually curated videos, we likely stripped away the very elements that make autoplay compelling in practice.

These results have implications for both research methodology and policy. Laboratory studies that isolate interface features from their natural digital ecosystem may fail to capture their real-world behavioral consequences. The controlled conditions necessary for internal validity inadvertently eliminate the personalized content that drives engagement on actual platforms. While autoplay shows no effect in our experimental setting, field studies suggest stronger impacts in natural usage contexts (Hiniker et al., 2018; Schaffner et al., 2025). Future research should prioritize better approximating genuine media consumption environments in the field (see e.g., Beknazar-Yuzbashev et al. (2025); Purohit et al. (2023)) while maintaining the control necessary for causal inference.

669 **A Additional Figures and Tables**

669

670 **Additional Figures**

670

Table A.1: Comparison of main sample vs flagged participants

	Main Sample N = 184	Flagged N = 40	<i>p</i> [M = F]
<i>Gender</i>			
Female	89 (48.37%)	13 (32.50%)	0.068*
<i>Age</i>			
Mean (SD)	42.29 (11.41)	42.85 (10.75)	0.768
<i>Employment</i>			
Employed (full time)	102 (55.43%)	27 (67.50%)	0.162
Employed (part time/self)	48 (26.09%)	8 (20.00%)	0.420
Not employed	34 (18.48%)	5 (12.50%)	0.366
<i>Income</i>			
Low (0-15)	56 (30.43%)	6 (15.00%)	0.048**
Middle (15-50)	103 (55.98%)	31 (77.50%)	0.012**
High (50+)	25 (13.59%)	3 (7.50%)	0.291
<i>Marital Status</i>			
Married/Partnership	95 (51.63%)	21 (52.50%)	0.921
Single	77 (41.85%)	17 (42.50%)	0.940
Previously married	12 (6.52%)	2 (5.00%)	0.719
<i>Treatment Assignment</i>			
Autoplay condition	79 (42.93%)	25 (62.50%)	0.025**

Note: This table compares demographic characteristics between the main sample (N=184) and participants flagged for potential inattention. Flagged participants reported engaging with videos but had mouse activity detected outside the experiment window, making it impossible to verify genuine engagement. *p*-values for binary outcomes are from two-sample tests of proportions; for continuous variables, from two-sample *t*-tests. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

Table A.2: Comparison of MPL sample vs main sample

	Main Sample N = 184	MPL N = 52	p [M = MPL]
<i>Gender</i>			
Female	89 (48.37%)	26 (50.00%)	0.835
<i>Age</i>			
Mean (SD)	42.29 (11.41)	41.90 (14.14)	0.858
<i>Employment</i>			
Employed (full time)	102 (55.43%)	32 (61.54%)	0.433
Employed (part time/self)	48 (26.09%)	10 (19.23%)	0.311
Not employed	34 (18.48%)	10 (19.23%)	0.902
<i>Income</i>			
Low (0-15)	56 (30.43%)	15 (28.85%)	0.825
Middle (15-50)	103 (55.98%)	30 (57.69%)	0.826
High (50+)	25 (13.59%)	7 (13.46%)	0.981
<i>Marital Status</i>			
Married/Partnership	95 (51.63%)	28 (53.85%)	0.778
Single	77 (41.85%)	19 (36.54%)	0.491
Previously married	12 (6.52%)	5 (9.62%)	0.446

Note: This table compares the demographic characteristics for the main sample (N=184) and the final MPL sample in block 2 (N=52). We observe no significant differences across the two samples.

Table A.3: *Autoplay* condition and time spent transcribing

	Transcription proportion (z-score)		
	(1)	(2)	(3)
Autoplay	0.136 (0.133)	0.055 (0.108)	0.055 (0.108)
Time Choice (z-score)		0.595*** (0.061)	0.580*** (0.089)
Autoplay $\times$ Time Choice			0.034 (0.119)
Constant	-0.063 (0.094)	-0.026 (0.078)	-0.027 (0.079)
Obs.	224	224	224
R^2	0.005	0.357	0.357
F -statistic	1.04	50.28	35.00

Note: Robust standard errors in parentheses. All variables are standardized. Time choice represents participants' planned transcription proportion from day 1. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

Table A.4: *Autoplay* condition and number of videos watched

	Nb. of Videos Watched (z-score)		
	(1)	(2)	(3)
Autoplay	0.051 (0.135)	0.131 (0.109)	0.132 (0.109)
Time Choice (z-score)		−0.590*** (0.060)	−0.555*** (0.084)
Autoplay × Time Choice			−0.077 (0.118)
Constant	−0.023 (0.090)	−0.061 (0.075)	−0.059 (0.075)
Obs.	224	224	224
R^2	0.001	0.347	0.348
F -statistic	0.14	48.91	34.21

Note: Robust standard errors in parentheses. All variables are standardized. Time Choice represents participants' planned typing proportion from day 1. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.
